

Reflection:

From my project, I received 1 peer review back. In this peer review, I received high marks and very little recommendations for improvement.

The notes I got were:

- Include warnings about improper indentation in the student copy of the instructions
- Include the commands on how to create the directory and enter it, essentially more instructions on setup.

What I did to correct these:

- I added the same note from the instructor instructions, and added it to the student instructions. I tried to add the warning before each code block to make sure the student did not forget.
- I added extra commands to be more specific on how to do the new directory, how to execute the commands, and how to execute the script.

What I added outside of the peer review:

- I actually had an over-engineered version of the script, since I went overboard at first and then reduced complexity later. Due to this, I have an extra script that operates more closely to real-life automation scripts than the lab one but it would be too complicated and long for an undergraduate lab. In this instance, I added the script and instructions under an optional step in the lab for the students who would like to review something more complex.
